A PROJECT ON

"TRAFFIC SIGNAL VIOLATION DETECTION SYSTEM"

Submitted in partial fulfilment for the award of the degree of

MASTER OF TECHNOLOGY IN INTEGRATED SOFTWARE ENGINEERING

BY

19MIS7050	KARTHIKEYA	GRANDHI	(TEAM LEAD)
-----------	------------	----------------	-------------

19MIS7097 SANKA SAI LALITHA SRAVANTHI

19MIS7092 GONTLA SRI LIKITHA

Under Guidance of

Dr. Anupama Namburu

CERTIFICATE

This is to certify that the Summer Project work titled "TRAFFIC SIGNAL VIOLATION DETECTION SYSTEM" that is being submitted by VENKATA KARTHIKEYA KRISHNA SAI MANIDEEP GRANDHI (19MIS7050) SANKA SAI LALITHA SRAVANTHI (19MIS7097) GONTLA SRI LIKITHA (19MIS7092) is in partial fulfilment of the requirements for the award of Master of Technology, is a record of bonafide work done under our guidance. The contents of this Project work, in full or in parts, have neither been taken from any other source nor have been submitted to any other Institute or University for award of any degree or diploma and the same is certified. The Project report fulfils the requirements and regulations of vit-ap and in our opinion it meets the necessary standards for submission.

Signature of the Guide

(Dr. Anupama Namburu)

ACKNOWLEDGEMENTS

It is our pleasure to express with deep sense of gratitude to **Dr. Anupama Namburu**, Associate

Professor, School of Computer Science and Engineering, VIT-AP, for her constant guidance,

continual encouragement, and understanding and more than all she taught us patience in our

endeavour. Our association with her is not confined to academics only, but it is a great

opportunity on our part of work with an intellectual and expert in the field of Computer Science

and Engineering.

We would like to express our gratitude to Dr. G. Viswanathan, Chancellor, Dr. Sekar

Viswanathan, VP, Dr. Sandhya Pentareddy, Executive Director, Dr. S V Kota Reddy, VC,

and **Dr. Sudha S V**, Dean, School of Engineering VIT-AP, for providing with an environment

to work in and for his inspiration during the tenure of the course.

In jubilant mood, we express ingeniously our whole-hearted thanks to **Dr. Reeja S R**, Program

Chair and Associate Professor, all teaching staff and members working as limbs of our

university for their not-self-centred enthusiasm coupled with timely encouragements showered

on us with zeal, which prompted the acquirement of the requisite knowledge to finalize our

course study successfully. We would like to thank our parents for their support.

It is indeed a pleasure to thank our friends who persuaded and encouraged us to take up and

complete this task. At last, but not least, we express our gratitude and appreciation to all those

who have helped us directly or indirectly toward the successful completion of this project.

ABSTRACT

This project is to identify and detect the vehicles that violate the traffic signals by giving our own region of interest. So over all this project is mainly about object detection in a video using YOLOv3 algorithm.

Some types of traffic violations are like moving violations and non moving traffic violations. Driving offences which have fatalities are dangerous driving and inconsiderate driving. As the number of vehicles on the roads is increasing rapidly, this successively causes highly congested roads and serving as a reason to interrupt traffic rules by violating them. This results in a high number of road accidents. Traffic violation detection systems using computer vision are an awfully efficient tool to scale back traffic violations by tracking and penalizing.

The recent developments in vision systems have encouraged us to develop advanced computer vision applications suitable to embedded platforms. Within the embedded closed-circuit television, where memory and computing resources are limited, simple and efficient computer vision algorithms are required.

Object detection from a video in video footage which is recorded is the major task. Object detection method is used to identify required objects in videos and to cluster pixels of these objects. The detection of an object in video plays an important role in several applications specifically as video applications.

The proposed system was implemented using YOLOv3 object detection algorithm for traffic violation detections in a video like signal jump, and also detecting the number of vehicles selecting our own region

Keywords:

Object detection, yolo, vehicles,

1. INTRODUCTION

The increasing number of vehicles in cities can cause high volume of traffic, and implies that traffic violations become more critical nowadays round the world. This causes severe destruction of property and more accidents that will endanger the lives of the people.

To unravel this alarming problem and forestall such unfathomable consequences, traffic violation detection systems are needed. A traffic violation detection system must be realized in real-time because the authorities track the roads all the time.

Hence, traffic enforcers won't only be comfortable in implementing safe roads accurately, but also efficiently, because the traffic detection system detects violations faster than humans.

The system that we developed can detect light violation in a video as a video surveillance application. A user-friendly graphical interface is related to the system to create it simple for the user to control the system, monitor traffic and take action against the violations of traffic rules.

1.1. OBJECTIVE

The goal of the project is to automate the traffic signal violation detection system and make it easy to monitor the traffic and take action against the violated vehicle owner in a fast and efficient way. Detecting and tracking the vehicle and their activities accurately is the main priority of the system.

Computer vision-based detection is based on the principle of vehicle classification, environment awareness, and traffic violation detection. Detection system, the proposed architecture of surveillance system with intelligent detection and tracking of multiple vehicles from the surveillance input video using YOLOv3 as an object detection algorithm.

The main objective is to detect multiple vehicle violation detection and it gives a more detailed picture of concepts and technology involved in creating a traffic violation detection system using computer vision.

1.2. BACKGROUND AND LITERATURE SURVEY

Manually checking the violation made by vehicles is difficult in real life and troublesome and there is chance of mistakes made due to feeble and problematic human memory. Earlier the traffic violation detection was done by human traffic cops at signal junctions, which highly need human resources and presence at all times. This eventually became more difficult as there is highly increase in vehicles.

This made to trigger the need for detection systems which are specialized systems made for detecting types of violations. A new system was needed which can be operated all the time without any interpretation. So, there is high need for traffic violation detection systems now a days.

We need traffic violation detection system in order to detect violations made by people while driving vehicles and for identification of criminal offenses like signal jump, over speed driving.

A system that works with least or no human resource requirement and which can identify multiple violations with high accurate result is required. So, this is how traffic violation detection systems using computer vision came into highlight.

Traffic violation detection with computer vision is based on computer vision technologies such as image processing, artificial intelligence, machine learning and deep learning. This detects objects in digital images or videos with instances of semantic objects and class. This makes easy for traffic police to capture the traffic violations made by people even in small lanes to big highways.

It also saves a lot of time and makes work easier for traffic police personnel to mainly focus on other work. The computer vision-based object detection is mainly based on the principle of vehicle classification, environment awareness and traffic violation detection.

So, a detection system is proposed with architecture of surveillance system with intelligent detection and tracking of vehicles from given video using YOLOv3 as an object detection algorithm.

This is made through a neural network and an object detection model in classification of the moving objects into different respective classes.

1.3 ORGANIZATION OF THE REPORT

The remaining chapters of the project are described as follows:

- Chapter 2 discusses about the fundamentals of the detection system like image processing, YOLOv3.
- Chapter 3 is for the projects proposed system, working methodology, software and hardware requirements.
- Chapter 4 discusses about the results obtained after the project was successfully implemented.
- Chapter 5 concludes the project report with conclusion and future work.
- Chapter 6 consists of codes in the project.
- Chapter 7 gives the references.

2. FUNDAMENTALS OF TRAFFIC SIGNAL VIOLATION DETECTION SYSTEM

This Chapter describes about the fundamentals of the detection system like image processing, YOLOv3 algorithm.

2.1. IMAGE PROCESSING, OBJECT DETECTION AND IMAGE RECOGNITION

Image Processing: It is a method to transform a image into an enhanced image or to get some useful information from it by doing some operations on it. It is a process to transform the image into a digital format. The algorithms help to analyze images to get deep insights in computer vision use cases.

Object Detection: It is a computer vision method for identifying and locating instances of objects in images or videos. It can also be used to find number of objects in a particular scene and then determine and track their location precisely and accurately by labelling them.

The main difference between **image recognition** and object detection is that image recognition only assigns a label to an image whereas object detection draws a box around the object and also labels it. Object detection also predicts where the object is located and what label should be applied to it.

2.2. YOLOv3

It is version 3 of YOLO which stands for 'You only look once'. It is a method which considers object detection as a regression problem. It is a object detection algorithm in real-time that identifies the specific objects in images, videos and live feeds. It is an algorithm that uses the features of deep convolutional neural network to detect the objects which is implemented using the Keras or OpenCV libraries of deep learning.

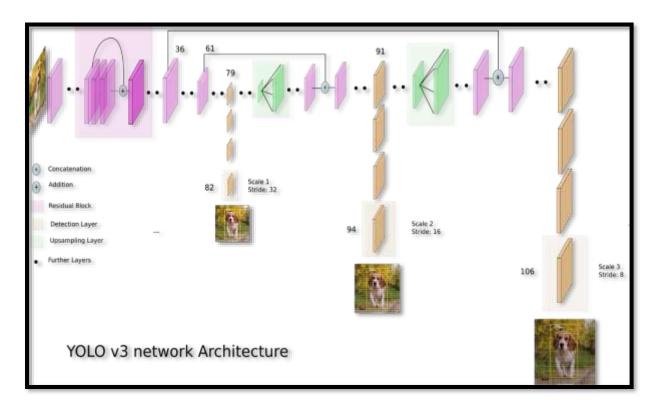

It predicts class probabilities as well as bounding box offsets directly from full images with a single feed forward convolution neural network. It eliminates region proposal generation and feature re-sampling, and encapsulates all stages in a single network.

YOLOv1 uses Darknet framework which is trained on ImageNet-1000 dataset. YOLOv2 uses Darknet-19 framework which contains 19 convolutional layers. But YOLO version 3 consists of 53 convolutional layers that are also called Darknet-53.

There are major differences between YOLOv3 and older versions occur in terms of speed, precision, accuracy, architecture and specificity of classes.

YOLOv3 can give the multi label classification since it uses a logistic classifier for each class in place of the SoftMax layer which is used in YOLOv2. As mentioned earlier YOLOv3 uses Darknet-53 framework which has fifty-three layers of convolution. These layers are more in detail and depth compared to Darknet-19 which used in YOLOv2. Darknet-53 mainly contains 3x3 and 1x1 filters along with by-pass links. The YOLOv3 is accurate version than YOLOv1, YOLOv2.

The architecture of YOLOv3 is shown here:

YOLO runs a lot more faster than RCNN, Fast RCNN and Faster RCNN version algorithms due to its simple architecture. Because unlike RCNN algorithms it is trained to do the classification as well as bounding box regression at a same time.

YOLO uses a single neural network to the entire image. This helps to divide the image into regions and gives probabilities for all regions. After that it predicts the number of bounding boxes which covers the regions on the image and chooses the best ones according to the probabilities.

FEATURES IN YOLOV3:

1. Bounding Box Predictions:

It is a single network that predicts the objective score using the logistic regression where one means that complete overlap of bounding box is prior over the object. It will predict only one main bounding box for an object. There will be other bounding boxes prior to it with objectiveness score much more than threshold but lesser than the best bounding box.

2. Class Prediction:

It uses independent logistic classifier method for each class instead of a normal regular softmax layer. This is made to classify the multi-label classification. Each bounding box predicts the classes in the image using the multi-label classification.

3. Feature Extractor:

YOLO version 3, originally, consists of 53 convolutional layers that are also called Darknet-53. But for detection tasks the original architecture is added with 53 more layers which gives us 106 layers of architecture for YOLO version 3. So you will see the process of loading architecture that has 106 layers. The detections for objects are mainly made at three layers 82, 94 and 106.

4. Predictions Across Scales:

YOLOv3 predicts at three different scales which precisely given by down sampling all the dimensions of the given image by 32, 16 and 18 respectively. First detection is made at 82nd layer as it will down sampled by the network till 81 layers such that the 81st layer have stride of 32. Then other detections are made at 94 and 106 layers as shown in the architecture.

5. Better at detecting smaller objects:

The detection at different layers helps to identify the issues of detection of small objects which is a major issue in YOLOv2. Usually the 13*13 layer is for detecting the large objects in images or videos, similarly the 52*52 layer is for detecting smaller objects and as well as 26*26 layer is for detecting the medium objects.

3. DESIGN AND IMPLEMENTION OF DETECTION SYSTEM

This Chapter describes the proposed system of the detection system, the working methodology, and software and hardware requirements.

3.1. PROPOSED SYSTEM

The system is mainly divided into two parts:

- 1. Vehicle classification
- 2. Violation detection

3.1.1. VECHILE CLASSIFIATION

From the given video footage, the vehicles which violate the traffic signals are detected and images of those vehicles are classified. The object detection algorithm - YOLOv3 is the third version in YOLO (You Only Look Once) algorithms is used for this vehicle classification. It is mainly used to improve the accuracy and is more capable for detecting the objects that violate the system. Some of the features of algorithm that made it unique are: Bounding box predictions, Class prediction, Predictions across scales, Feature extractor.

The classifier model that we built is with Darknet-53 architecture which is as shown below.

	Туре	Filters	Size	Output
	Convolutional	32	3 × 3	256 × 256
	Convolutional	64	$3 \times 3/2$	128 × 128
- 1	Convolutional	32	1 × 1	
1×	Convolutional	64	3×3	
	Residual			128 x 128
	Convolutional	128	$3 \times 3/2$	64×64
	Convolutional	64	1 × 1	
2×	Convolutional	128	3 × 3	
	Residual		1999/00/00	64×64
	Convolutional	256	3×3/2	32 × 32
1	Convolutional	128	1 × 1	
8×	Convolutional	256	3×3	
	Residual			32×32
	Convolutional	512	3 × 3 / 2	16 x 16
	Convolutional	256	1 x 1	
8×	Convolutional	512	3×3	
	Residual			16 x 16
	Convolutional	1024	3×3/2	8 x 8
	Convolutional	512	1 × 1	
4×	Convolutional	1024	3×3	
	Residual			8 × 8
	Avgpool		Global	
	Connected		1000	
	Softmax			

Fig: Darknet-53 architecture

3.1.2 VIOLATION DETECTION

The vehicles which violate the traffic signal i.e. the region of interest that we give in the input video data are detected using YOLOv3 algorithm. After the image classification and detection of the vehicles the violation cases are checked.

A traffic line i.e region of interest is drawn on the road in the input video data by the user. This line tells that the traffic light is red and the driver need to stop. The violation happens if the vehicle crosses the region of interest in red state.

The identified vehicle objects are shown with a green bounding box. If any object passes the region of interest in red state, it is shown in bounding box with a different colour since the violation happened.

3.2. WORKING METHODOLOGY

The following diagram (figure) shows the system overview of this project:

The system mainly contains two components: Vehicle detection model and a graphical user interface i.e. GUI.

At first user selects the video footage of the vehicles and it is sent to the system. Then vehicles are detected from the given input video footage. The user now will draw the line which is region of interest. After tracking the activity of vehicles, system determines whether any violation is happened or not. If system detects any

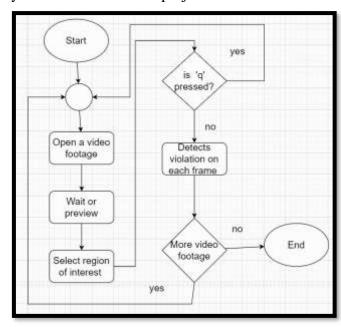

Fig: System overview

objects that violate the signal then it will capture that vehicle and store it in the database folder.

The GUI makes the system more interactive and helps the user to use it easily. User can view the traffic footage and can get the output with an alert of violation as a bounding box around the violated vehicle. User can also take further action using the GUI.

The below figure shown describes about the system functions.

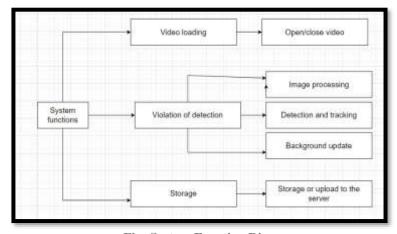

Fig: System Function Diagram

System can load the video footage then open or close video. The violation detection is divided as image preprocessing, detection and tracking, background update in the database. It stores the output by a bounding box around the object.

3.3. STANDARDS

Various standards used in this project are as follows:

- TensorFlow: It is an end-to-end open-source platform for machine learning. It has a
 comprehensive, flexible ecosystem of tools, libraries and community resources that lets
 researchers push the state-of-the-art in ML and developers easily build and deploy ML
 powered applications.
- Numpy: It is a library in python programming language, adding support for large, multi-dimensional array and matrices, along with a large collection of high-level mathematical functions to operate on these arrays.
- Pandas: Pandas allows us to analyze big data and make conclusions based on statistical
 theories. Pandas can clean messy data sets, and make them readable and relevant.
 Relevant data is very important in data science. Pandas are also able to delete rows that
 are not relevant, or contains wrong values, like empty or NULL values. This is
 called cleaning the data.
- Keras: Keras is a minimalist Python library for deep learning that can run on top of
 Theano or TensorFlow and also powerful and easy-to-use free open-source Python
 library for developing and evaluating deep learning models.

 It is part of the TensorFlow library and allows you to define and train neural network
 models in just a few lines of code.
- **Struct:** The module struct is used to convert the native data types of python into string of bytes and vice versa. We don't have to install it. It's a built-in module available in Python3.
- OpenCV: OpenCV (Open-Source Computer Vision Library) is an open-source computer vision and machine learning software library. OpenCV was built to provide a common infrastructure for computer vision applications and to accelerate the use of machine perception in the commercial products.
- **Tkinter:** Tkinter is the standard GUI library for Python. Python when combined with Tkinter provides a fast and easy way to create GUI applications. Tkinter provides a powerful object-oriented interface to the Tk GUI toolkit.
- Imageio: Imageio is a Python library that provides an easy interface to read and write a wide range of image data, including animated images, volumetric data, and scientific formats.

3.4. REQUIREMENTS

The software requirements for this project are as follows:

- Operating system Windows 7 is used as the operating system as it is stable and supports more features and is more user friendly
- Development tools & Programming language PYTHON is used to write the whole code and visual studio code has been used for development

Software	Minimum System Requirement	
Operating System	Windows 7 (or) Later	
Runtime Server	Visual Studio Code	

The hardware requirements for this project are as follows:

- INTEL CORE I3 2ND GENERATION is the least that can be used as a processor because it is fast than other processors an provide reliable and stable and we can run our pc for long time. By using this processor, we can keep on developing our project without any worries.
- RAM 1 GB is used as it will provide fast reading and writing capabilities and will in turn support in processing

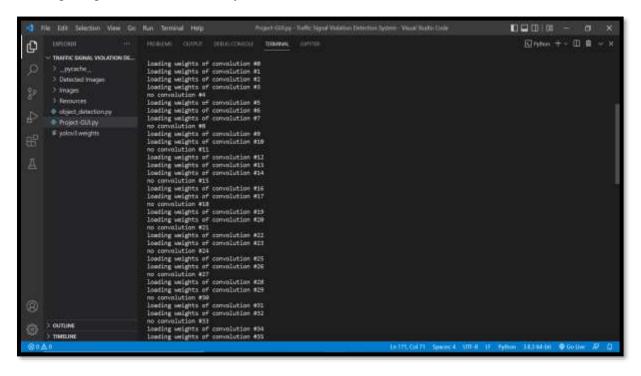

Hardware	Minimum System Requirement
Processor	Intel i3
Memory	128 MB RAM
Disk	10 GIGA BYTE

The interface requirements for this project are as follows:

- Easy to navigate & Less graphics
- Display error messages and relevant dialogue boxes
- Provide high security such that no to be modified by irrelevant users
- It must provide all options to all users.

4. RESULTS

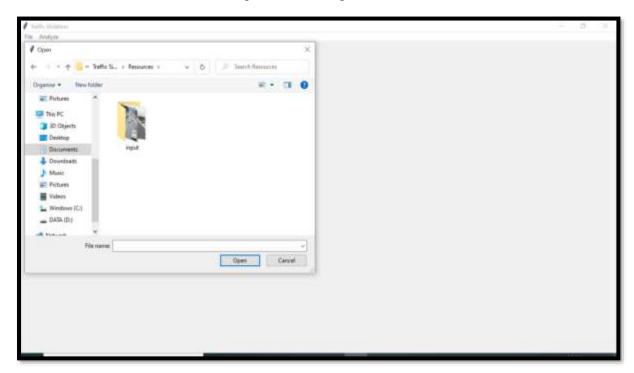

Loading weights of convolution layers:

This is the GUI home page with have 'File' and 'Analyse' options. Further the file have 'Open' and 'Exit' options and analyse have 'Region of interest' option.

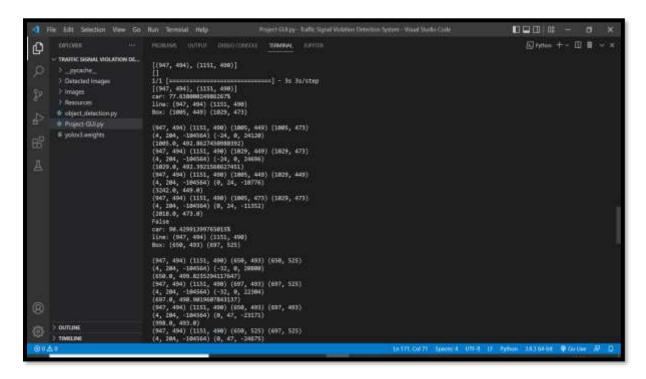

Selecting a video footage from folder:

Drawing region of interest after selecting video:

Execution after drawing region of interest:

All the vehicles are detected, labelled and localized. The blue colour line here is region of interest.

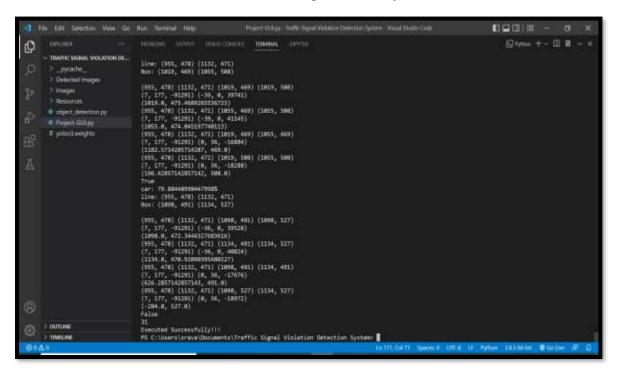

Detection of vehicles which violates the rule by crossing region of interest:

After successfully executing entire video the region of interest turns into green from blue and now we can exit from the system.

After executing successfully:

5.1. CONCLUSION

The detection of vehicles which violates traffic signals in a video footage is a challenging task as the vehicles that travel on road and traffic rules for them are depended on the different regions of the roads and their timings. In this project we proposed that YOLO algorithm with version 3 is much suitable for traffic signal violation detection.

The final output shown that the detection of many traffic violations forms a single input source is also possible. The detection time is much lower for the high denser traffic flow. Thus, the detection system operation speed depends on the density of the traffic.

5.2. FUTURE WORK

The system runtime is a little slow, and can be improved using a computer with much higher speed processor specification. Future research can be done for the system by other advanced image processing techniques. Further improvements are needed to decrease computational time of the detection system at high the traffic volume roads. This project can be developed in future to implement a number plate detection of detected vehicles in the video footage.

6. APPENDICES - CODE
